# MFE R Programming Workshop Week 5

Brett Dunn and Mahyar Kargar

Fall 2017

## Introduction

## Questions

Any questions before we start?

#### Overview of Week 2

- Some random R tricks
- Importing Data from Databases
- Importing Data from the Web
- ► Importing Data from WRDS
- ▶ data.table

## Random R Tricks

#### Send an Email from R

```
library(gmailr)
hiFromR <- mime(
   To = "someone@anderson.ucla.edu",
   From = "me@gmail.com",
   Subject = "hello from R",
   Body = "I am writting you from R."
) %>%
attach_file("./file.R")
send_message(hiFromR)
```

## Working with Files in R

```
dir.exists("week3") # does the directory exist?
dir.create("week4") # create a directory
# download files
download.file(url, destinationfile, method='curl')
untar() # untar a file
tar() # tar a file
# display file information
f<-(dir("/path/to/something", full.names = TRUE) %>% file.:
# delete a file (be careful!!)
unlink("/path/to/something")
```

# Importing Data from Databases

#### **Databases**

- A database stores data in table format.
- ► There a several popular database management systems (DMS):
  - MySQL, PostgreSQL, SQLite, Oracle, Microsoft SQL Server, etc.
- Structured Query Language (SQL) is used maintain and query the database.

#### Databases in R

- ▶ There are different R packages for each DMS:
  - ► MySQL = RMySQL
  - PostgreSQL = RPostgreSQL
  - ► SQLite = RSQLite
  - ► Oracle = ROracle
  - SQL Server = RSQLServer
- The functions we use to interact with the database are specified in the R package DBI.

## A MySQL Example: Establish a Connection

▶ First, we need to establish a connection to the database.

## List and Import Tables

```
# lists the tables in the database
dbListTables(con)
# returns a dataframe
dbReadTable(con, "tablename")
# import all the tables
table_names <- dbListTables(con)
tables <- lapply(table_names, dbReadTable, conn = con)
# close the connection when you are done
dbDisconnect(con)</pre>
```

# Importing Data From the Web

#### **JSON**

- ▶ JSON object: an unordered collection of name-value pairs.
- ▶ JSON array: an ordered sequence of zero or more values.
- ▶ JSON objects and arrays can be nested in each other.
- ▶ R handles JSON with the jsonlite package.

## An Example with 'jsonlite'

## [1] "false"

Let's get the current wind and delay status at LAX.

```
library(jsonlite)
airportCode <- "LAX"
url <- paste0("http://services.faa.gov/airport/status/",</pre>
               airportCode)
LAX <- from JSON(url)
LAX$weather$wind
## [1] "West at 16.1mph"
LAX$delay
```

15 / 53

## Quandl

- Quandl is a useful source of financial data and there is an R package Quandl to import the data into R.
- ► See https://www.quandl.com/tools/r.
- ▶ Data can be downloaded as xts objects, datatables, etc.

```
library(Quand1)
# download GDP as an xts object
gdp <- Quand1("FRED/GDP", type="xts")
last(gdp, 2)</pre>
```

# Importing Data from WRDS

## WRDS, CRSP, and R

- Wharton Research Data Services has over 250 terabytes of data.
- One data provider is The Center for Research in Security Prices (CRSP).
  - You will use CRSP data throughout the MFE program.
- I will show you how to access WRDS from R.
- Documentation: Using R with WRDS

## Setup

- ▶ First, we need to obtain access to WRDS and download the SAS drivers for JDBC from here.
- The two files should be saved locally.
- ► Take note of the path to the files; we need the path to establish the connection to WRDS.

#### Establish the Connection

```
# ---- TNPUTS ---- #
username <- "myUserName"
password <- "myPassword"</pre>
# local path to the sas files
sasPath <- "C:/Users/myUser/Documents/wrds-drivers"</pre>
# ---- CODE ---- #
library(rJava)
options(java.parameters = '-Xmx4g')
library(RJDBC)
sasCore <- pasteO(sasPath, "/sas.core.jar")</pre>
sasDriver <- paste0(sasPath, "/sas.intrnet.javatools.jar")</pre>
.jaddClassPath(c(sasCore, sasDriver))
driver <- RJDBC::JDBC(</pre>
         "com.sas.net.sharenet.ShareNetDriver",
          sasDriver, identifier.quote = "`")
wrds <- RJDBC::dbConnect(driver,</pre>
"jdbc:sharenet://wrds-cloud.wharton.upenn.edu:8551/",
username, password)
```

## Accessing Data

On the previous slide, we created the connection wrds.

```
res <- dbSendQuery(wrds, "select * from DATASET")
data <- fetch(res, n = -1)
data</pre>
```

- dbSendQuery() uses wrds to submit the SQL query string to WRDS, which then returns the result res.
- select \* from DATASET is a SAS SQL query.
  - See the SAS SQL Documentation for more information.
- ▶ fetch() fetches the actual data based on the result res.
- ▶ n = -1 is a parameter that determines how many observations to download.
  - ▶ n = -1 specifies that we'd like unlimited observations returned.
  - ightharpoonup n = 10 would limit the number of observations returned to 10.

## Example: S&P 500 Returns

```
sql <- "SELECT caldt, vwretd FROM CRSPQ.MSP500"
res <- dbSendQuery(wrds, sql)
dbHasCompleted(res) #check that this is true
msp500 \leftarrow fetch(res, n = -1)
dbClearResult(res) # free up memory
msp500$caldt <- as.Date(msp500$caldt)</pre>
library(xts)
msp500 <- xts::xts(msp500[, -1],
                    order.by = msp500$caldt)
colnames(msp500) <- "vwretd"</pre>
```

data.table

#### What is a data.table?

- ▶ Think of data.table as an advanced version of data.frame.
  - ▶ Every column is the same length, but may have a different type
- ▶ It inherits from data.frame and works perfectly even when data.frame syntax is applied on data.table.
- data.table is very fast.
- ▶ The syntax of data.table is very concise.
  - Lowers programmer time...
  - ... but it can be hard to understand
  - Make sure you comment your code!

#### library(data.table)

## An Example

- Syntax is DT[i, j, by]
- ► Take DT, subset rows using i, then calculate j grouped by by.

```
data("mtcars")
mtcarsDT <- data.table(mtcars)
mtcarsDT[
   mpg > 20,
   .(AvgHP = mean(hp),
      "MinWT(kg)" = min(wt*453.6)),
   by = .(cyl, under5gears = gear < 5)]</pre>
```

```
## cyl under5gears AvgHP MinWT(kg)
## 1: 6 TRUE 110.00000 1188.4320
## 2: 4 TRUE 78.33333 732.5640
## 3: 4 FALSE 102.00000 686.2968
```

### Types in R

## [1] "integer"

Character columns are very efficient in R.

```
typeof(1)
## [1] "double"
typeof(1L)
## [1] "integer"
typeof(NA)
## [1] "logical"
typeof(NA_integer_)
```

## Creating a data.table

```
## 1: 1 a 0.73635205 FALSE
## 2: 2 b 0.26499071 FALSE
## 3: 3 c 0.25536397 FALSE
## 4: 4 a 0.61080258 FALSE
## 5: 5 b 0.04726397 FALSE
## 6: 6 c 0.13604891 FALSE
```

## Selecting Rows by Number in i

▶ The comma is optional.

```
DT[2:4,]
## A B
## 1: 2 b 0.2649907 FALSE
## 2: 3 c 0.2553640 FALSE
## 3: 4 a 0.6108026 FALSE
DT[2:4]
## AB C
## 1: 2 b 0.2649907 FALSE
## 2: 3 c 0.2553640 FALSE
## 3: 4 a 0.6108026 FALSE
```

## Selecting Columns in j

- Columns are specified as a list with the actual names, not as character vectors.
- .() is an alias to list() in data.tables.

```
DT[2:3, list(A, C)]

## A C
## 1: 2 0.2649907
## 2: 3 0.2553640

DT[2:3, .(A, C)]
```

```
## A C
## 1: 2 0.2649907
## 2: 3 0.2553640
```

## Selecting Columns in **j** with character vectors

► To select columns with a character vector, set the with argument to FALSE.

```
DT[2:3, c("A", "C"), with=FALSE]
```

```
## A C
## 1: 2 0.2649907
## 2: 3 0.2553640
```

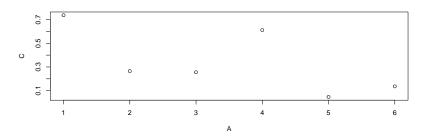

## Computing on Columns

▶ If the lengths of the results are not equal, the shorter one will be recycled.

```
DT[, .(Total = sum(A), Mean = mean(C))]
##
     Total Mean
## 1: 21 0.3418037
DT[2:4, .(B, Mean = mean(C))]
## B
            Mean
## 1: b 0.3770524
## 2: c 0.3770524
## 3: a 0.3770524
```

## You can put almost anything into j

DT[, plot(A, C)]

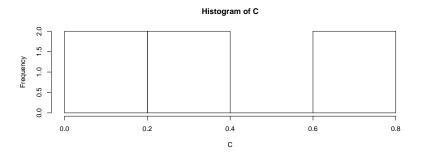

## NULL

## Multiple Expressions Go in Curly Braces

```
DT[, {print(A)
     hist(C)
     NULL}] # set return value to NULL
```

## [1] 1 2 3 4 5 6

## NULL

## Returning a Vector.

```
DT[, .(A)] # a data.table
## A
## 1: 1
## 2: 2
## 3: 3
## 4: 4
## 5: 5
## 6: 6
DT[, A] # a vector
## [1] 1 2 3 4 5 6
```

## Doing j by Group

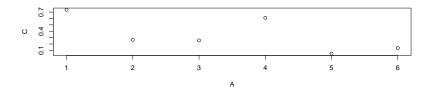

```
## B Total Mean
## 1: a 5 0.6735773
## 2: b 7 0.1561273
## 3: c 9 0.1957064
# functions work as well
DT[, .(Total = sum(C)), by = .(Group = A\(\frac{1}{2}\)2)]
## Group Total
## 1: 1 1.038980
## 2: 0 1.011842
```

#### .N

- . N, when used inside square brackets, contains the number of rows.
- ▶ When put in  $\mathbf{j}$ , . N counts the observations in each group.

```
DT[.N] # the last row, the same as DT[nrow(DT)]
## AB C
                     D
## 1: 6 c 0.1360489 FALSE
DT[, .(Total = sum(C), Count = .N), by = .(Group = A\\\2)
     Group Total Count
##
## 1: 1 1.038980
                      3
## 2: 0 1.011842
                      3
```

# Operations can be Chained Together

```
## Group Total Count
## 1: 1 1.038980 3
## 2: 0 1.011842 3
```

#### Subset of Data - .SD

- .SD is a data.table.
- SD holds all the columns except for the one specified in by, and .SD is only accessible in j.
- ► This is very useful if you have a very wide data.table.
- SDcols allows you to apply a function to a subset of the columns.

```
DT <- as.data.table(iris)
DT[, lapply(.SD, median), by = Species]</pre>
```

Since lapply returns a list, we don't need to wrap it in .().

# Add or Update Columns by Reference Using :=

```
DT <- data.table(A=1:3, B=4:6)
DT

## A B
## 1: 1 4
## 2: 2 5
## 3: 3 6

DT[, c("A", "C") := .(rev(A), 7:9)]
```

# Remove Columns Using :=

We use NULL to remove columns.

```
DT[, D := 10:12]
DT[, c("B", "C") := NULL]
```

▶ Wrap the LHS in () if you pass a variable.

# Combining := with i and by

```
DT <- data.table(A=1:6, B=c("a", "b", "c"), C=runif(6))
DT[1:5, D := sum(C), by=B]</pre>
```

### Use set() in Loops.

- set() is a loopable, low-overhead version, of the := operator, but it cannot handle grouping.
- Syntax: set(DT, i, j, value).
- ▶ Instead of for (i in 1:6) DT[i, z := i+1] we can

```
DT <- data.table(A=7:12, B=7:12)
for (i in 1:6) set(DT, i, 2L, i+1)
DT</pre>
```

```
## A B
## 1: 7 2
## 2: 8 3
## 3: 9 4
## 4: 10 5
## 5: 11 6
## 6: 12 7
```

# setnames() to Change the Column Names

setnames(DT, "old", "new") changes the column names by reference (no copies are being made).

```
setnames(DT,c("A", "B"),c("X", "Y"))
DT
```

```
## X Y ## 1: 7 2 ## 2: 8 3 ## 3: 9 4 ## 4: 10 5 ## 5: 11 6 ## 6: 12 7
```

## setcolorder() Reorders the Columns by Reference

```
setcolorder(DT,c("Y", "X"))
DT
```

```
## Y X
## 1: 2 7
## 2: 3 8
## 3: 4 9
## 4: 5 10
## 5: 6 11
## 6: 7 12
```

# Using Column Names in i

```
DT \leftarrow data.table(A=1:6, B=c("a", "b", "c"),
                 C=runif(6), D=FALSE)
DT[B %in% c("a", "b")]
## A B C
## 1: 1 a 0.61556924 FALSE
## 2: 2 b 0.17841027 FALSE
## 3: 4 a 0.06741918 FALSE
## 4: 5 b 0.32598186 FALSE
```

#### Regular Expressions

- Metacharacters allow you to match certain types of characters.
  - ► For example, . means any single character, ^ means "begins with", and \$ means "ends with".
- ▶ If you want to use any of the metacharacters as actual text, you need to use the \ escape sequence.
- See ?gsub() and ?grep().

```
iris <- as.data.table(iris)
# Change column names
setnames(iris, names(iris), gsub("^Sepal\\.", "", names(iris)
# Remove columns
iris[, grep("^Petal", names(iris)) := NULL]</pre>
```

## Keys

Setting a key sorts the table by the column specified.

```
DT <- data.table(A=c("c", "b", "a"),B=1:6)
setkey(DT, A)
DT</pre>
```

```
## A B
## 1: a 3
## 2: a 6
## 3: b 2
## 4: b 5
## 5: c 1
## 6: c 4
```

# Keys as Row Names

## 1: a 6

Keys can be used like row names.

```
DT["a"]
## A B
## 1: a 3
## 2: a 6
DT["a", mult = "first"]
## A B
## 1: a 3
DT["a", mult = "last"]
## A B
```

#### nomatch

Keys can be used like row names.

```
DT[c("a", "d")]
## A B
## 1: a 3
## 2: a 6
## 3: d NA
DT[c("a","d"), nomatch = 0]
## A B
## 1: a 3
## 2: a 6
```

## Multi-Column Keys

▶ Use .() to select rows.

```
DT \leftarrow data.table(A=c("c", "b", "a"),B=1:6,C=7:12)
setkey(DT, A, B)
DT[.("b")]
## A B C
## 1: b 2 8
## 2: b 5 11
DT[.("b", 5)]
## A B C
## 1: b 5 11
```

# Converting xts objects to data.tables

```
library(xts)
x \leftarrow matrix(1:4, nrow=2, ncol=2)
idx <- seq(as.Date("2016-10-31"), length=2, by="months")
x_xts \leftarrow xts(x, order.by = idx)
x_xts
##
              [,1] [,2]
## 2016-10-31 1 3
## 2016-12-01 2
colnames(x xts) <- c("a", "b")</pre>
DT <- as.data.table(x xts)
setkey(DT,index)
DΤ
##
           index a b
```

## 1: 2016-10-31 1 3 ## 2: 2016-12-01 2 4

### Rolling Joins

- Rolling joins are useful for time-series data.
- See rollends in ?data.table.

```
DT
##
           index a b
## 1: 2016-10-31 1 3
## 2: 2016-12-01 2 4
dt \leftarrow as.Date("2016-11-15"): DT[.(dt)]
##
           index a b
## 1: 2016-11-15 NA NA
DT[.(dt), roll=TRUE] # roll forward; try roll=-Inf.
##
           index a b
## 1: 2016-11-15 1 3
```

#### Lab 3

Let's work on Lab 3.
